Markov chain - Wikipedia
Thus, a continuous-time Markov chain is a stochastic process such that (i), its transition from one state to another state of the state space S, is as in a discrete-time Markov chain and (ii) the sojourn in a state i (holding time in state i before moving to another state) is an exponential RV whose parameter depends on i but not on the state next visited. The sojourn times in different states must be independent random variables with exponential distribution.

Continuous Time Markov Chain - an overview | ScienceDirect ...
Continuous Time Markov Chains In a continuous time Markov chain, the state transitions may occur at any time, and the time between transitions is exponentially distributed. Since the exponential distribution is memoryless, the future outcome of the process depends only on the present state and does not depend on when the last transition occurred or what any of the previous states were.

2 Counting processes and continuous time Markov chains The simplest counting process is a Poisson process, and Poisson processes will be the basic building blocks that we use to obtain more complex models. 2.1 Poisson processes A Poisson process is a model for a series of random observations occurring in time. x x x x x x x x t

25 Continuous-Time Markov Chains - Introduction
Markov chains and continuous-time Markov processes are useful in chemistry when physical systems closely approximate the Markov property. For example, imagine a large number n of molecules in solution in state A, each of which can undergo a chemical reaction to state B with a certain average rate. Perhaps the molecule is an enzyme, and the states refer to how it is folded.

CONTINUOUS-TIME MARKOV CHAINS - University of Chicago
Continuous time Markov Chains are used to represent population growth, epidemics, queueing models, reliability of mechanical systems, etc. In Continuous time Markov Process, the time is perturbed by exponentially distributed holding times in each

What is the difference between all types of Markov Chains?
CONTINUOUS TIME MARKOV CHAINS STEVEN P. LALLEY 1. Introduction Discrete-time Markov chains are useful in simulation, since updating algorithms are easier to construct in discrete steps. They can also be useful as crude models of physical, biological, and social processes. However, in the physical and biological worlds time runs continuously,

Chapter 6 Continuous Time Markov Chains - BIU
Just as with discrete time, a continuous-time stochastic process is a Markov process if the conditional probability of a future event given the present state and additional information about past states depends only on the present state.

1 IEOR 6711: Continuous-Time Markov Chains
A Markov chain is inherently discrete. A continuous-time Markov chain, while the notion is not all that well poised, might be something like a finite element method. An alternative answer to your question is that there's a rule of thumb about the tradeoff between discretization (i.e. computability in many cases) and accuracy.

What are the differences between a Markov chain in ...
A continuous-time Markov chain is one in which changes to the system can happen at any time along a continuous interval. An example is the number of cars that have visited a drive-through at a local fast-food restaurant during the day.

Continuous time Markov chain models for chemical reaction ...
be called a continuous-time Markvov chain (CTMC), and as we will conclude shortly, the holding times will have to be exponentially distributed. The formal de nition is given by

Continuous Time Markov Chains And
continuous-time Markov chain is defined in the text (which we will also look at), but the above description is equivalent to saying the process is a time-homogeneous, continuous-time Markov chain, and it

Continuous-time Markov chains
Continuous Time Markov Chains We enhance Discrete-Time Markov Chains with real time and discuss how the resulting modelling formalism evolves over time. We compute the steady-state for different kinds of CMTCs and discuss how the transient probabilities can be efficiently computed using a method called uniformisation.

CONTINUOUS-TIME MARKOV CHAINS
Based on the embedded Markov chain all properties of the continuous Markov chain may be deduced. TheoremLet V_{ij} denote the transition probabilities of the embedded Markov chain and q_{ij} the rates of the infinitesimal generator. The transition probabilities of the corresponding continuous-time Markov chain are found as

continuous time markov
Let $X(t)$ be a continuous-time Markov chain that starts in state $X(0)=x$. Then conditional on T and $X(T)=y$, the post-jump process (12) $X^{\leftarrow}(s):=X(T+s)$ is itself a continuous-time Markov chain with the transition probabilities P s and initial state y. More precisely, there exists a stochastic matrix A =(a x,y) such that for all times s 0 and 0=t 0 <t 1 <t

Continuous Time Markov Chains - University of Texas at Dallas
continuous Markov chains... Construction3.A continuous-time homogeneous Markov chain is determined by its infinitesimal transition probabilities: $P_{ij}(h) = hq_{ij} +o(h)$ for $j \neq 0$ $P_{ii}(h) = 1-h\nu_i +o(h)$ • This can be used to simulate approximate sample paths by discretizing time into small intervals (the Euler method).

Continuous Time Markov Chains (CTMCs) Memoryless property Continuous Time Markov Chains (CTMCs) Memoryless property In fact, the preceding gives us another way of de ning a continuous-time Markov chain. Namely, it is a stochastic process having the properties that each time it enters state i (i)the amount of time it spends in that state before making a

A continuous time Markov chain is determined by the matrices P t. The fact that we now have a continuous parameter for time allows us to apply notions from calculus to continuous Markov chains

in a way that was not possible in the discrete time chain. However, it also creates a number of technical issues

5. Continuous-time Markov Chains - Statistics

An algorithmic construction of a general continuous time Markov chain should now be apparent, and will involve two building blocks. The first will be a stream of unit exponential random variables used to construct our holding times, and the second will be a discrete time Markov chain, denoted X_n, with transition probabilities p
